

## Small-world & scale-free models, graphs vs networks

---

You are given four networks in Pajek format (edge list and LNA formats are also available).

- A simple [toy network](#) for testing (tiny)
- The famous [Zachary karate club network](#) (small)
- [iMDB actors collaboration network](#) (medium)
- A part of [Google web graph](#) (large)

### I. Watts-Strogatz small-world networks

1. Study the algorithm for generating Watts-Strogatz small-world networks  $G(n, k, p)$  introduced in lectures. Does the algorithm generate networks with realistic structure? What is the time complexity of the algorithm?
2. Try to implement the algorithm and generate Watts-Strogatz small-world networks corresponding to smaller networks above. Compute their average clustering coefficient  $\langle C \rangle$  and the average distance between the nodes  $\langle d \rangle$ . Are the results expected or are they surprising?

### II. Barabási-Albert and Price scale-free networks

1. Study the following two algorithms for generating Barabási-Albert scale-free networks  $G(n, c)$  and Price scale-free networks  $G(n, c, a)$  based on the equality  $\frac{q+a}{n(c+a)} = \frac{c}{c+a} \frac{q}{nc} + \frac{a}{c+a} \frac{1}{n}$ . What is the main difference between the algorithms? What is the time complexity of the algorithms?

<b>input</b> nodes $n$ , degree $c$	<b>input</b> nodes $n$ , out-degree $c$ , free $a$
<b>output</b> <i>undirected scale-free</i> $G$	<b>output</b> <i>directed scale-free</i> $G$
1: $Q \leftarrow$ empty queue	1: $Q \leftarrow$ empty queue
2: $G \leftarrow$ empty graph	2: $G \leftarrow c$ isolated nodes
3: <b>while not</b> $G$ has $n$ nodes <b>do</b>	3: <b>while not</b> $G$ has $n$ nodes <b>do</b>
4: $i \leftarrow$ add node to $G$	4: $i \leftarrow$ add node to $G$
5: <b>for</b> $c$ times <b>do</b>	5: <b>for</b> $c$ times <b>do</b>
6: $Q.add(i)$	6: <b>if</b> $[0, 1).random() < c/(c + a)$ <b>then</b>
7: $Q.add(j \leftarrow Q.random())$	7: $Q.add(j \leftarrow Q.random())$
8:         add link between $i$ and $j$	8: <b>else</b>
9: <b>return</b> $G$	9: $Q.add(j \leftarrow \{0, \dots, i\}.random())$
	10:         add link from $i$ to $j$
	11: <b>return</b> $G$

2. Try to implement one of the algorithms and generate Barabási-Albert or Price scale-free networks

corresponding to larger networks above. Plot their degree distributions  $p_k$  and compute the power-law exponents  $\gamma$  of seemingly scale-free distributions. Are the results expected or are they surprising?

### III. Synthetic random graphs vs real networks

Consider different large-scale properties of real networks. Namely, low average node degree  $\langle k \rangle \ll n$ , single giant connected component  $S \approx 1$ , low average distance between the nodes  $\langle d \rangle \approx \frac{\ln n}{\ln \langle k \rangle}$ , high average clustering coefficient  $\langle C \rangle \gg 0$  and power-law degree distribution  $p_k \sim k^{-\gamma}$ .

1. Try to design a synthetic graph model that generates undirected graphs that are *most different* from real networks.
2. Try to implement a generative graph model that *best reproduces* the structure of real undirected networks.
3. Does your model have a reasonable interpretation or explanation? Does it also reproduce the structure of real directed networks?
